Yukon, Kuskokwim, Nushagak Rivers

Chinook Catch Index, 1961-2005

Hypotheses:

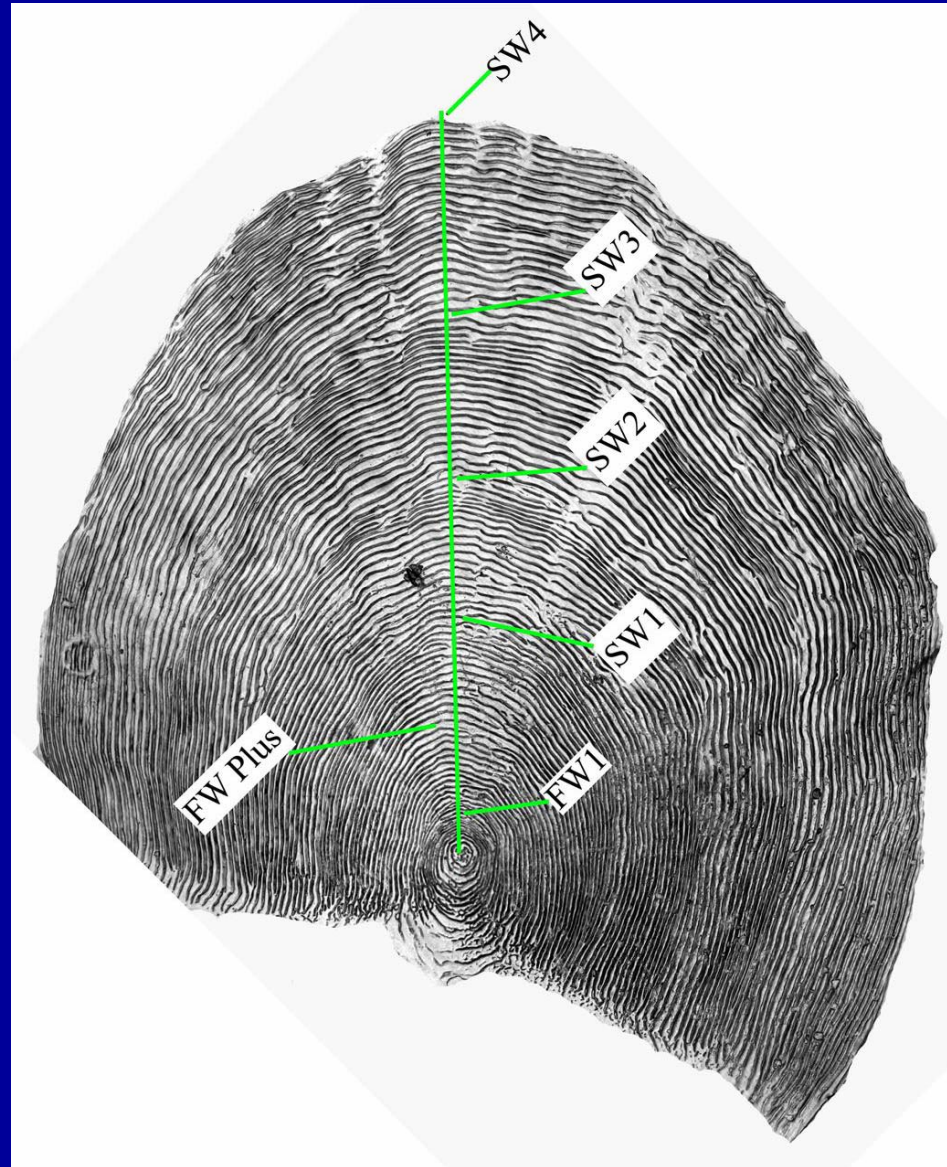

- Low Chinook abundance is associated with low growth in freshwater &/or the ocean.
- Chinook growth is associated with climate shifts (1976/77, 1997).
- Annual growth is independent of previous growth.
- Growth of male versus female Chinook is equal.

Chinook Scale Measurements

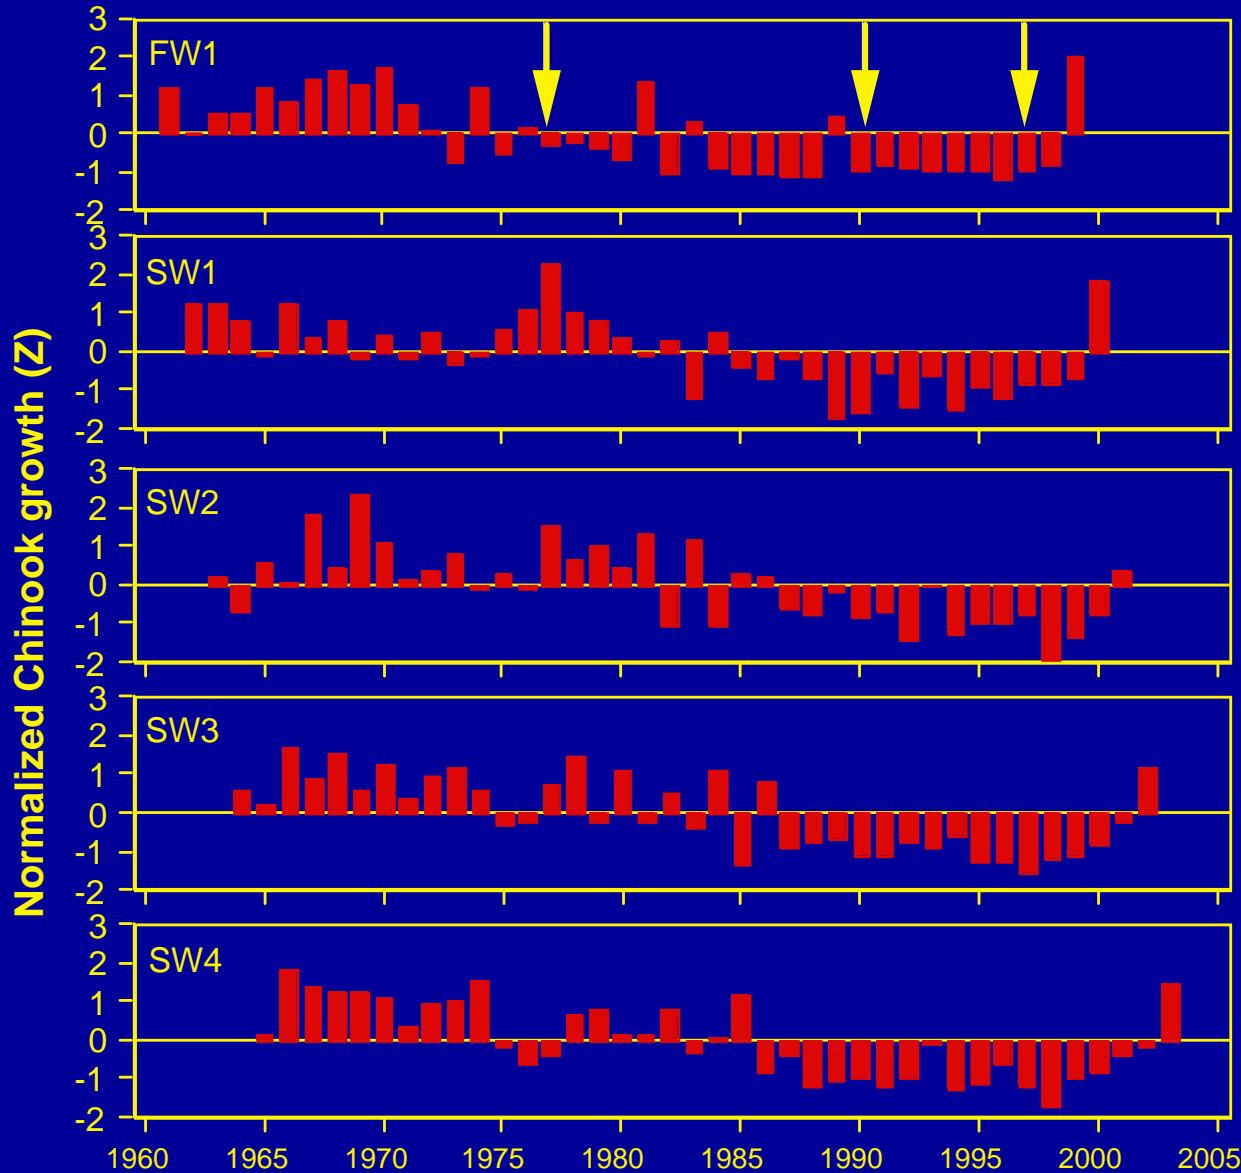

- Yukon & Kuskokwim Chinook, ~1964-2004.
- Age-1.3 & -1.4.
- 25 male & 25 female per year, age, stock.
- 200 scales per year.

Annuli & Circuli Measurements

Annual Yukon Scale Growth: Year of Growth

- Scale growth does not clearly reflect climate shifts.
- Growth dependency?.

Ocean Growth is Dependent on Freshwater Growth

Year: 1991

Growth at Sea Dependent on Previous Growth

Year: 1991

Growth Dependent on Previous Growth: Mean slope, ~1960-2004

690 regression

Compensatory Growth: (mortality and/or physiology?)

Adult Length
Correlated
with Scale
Growth

Adult length
weakly
correlated with
freshwater
growth

Chinook Growth is Dependent on Previous Growth

WHY?

- Chinook are piscivorous at early age (Farley et al.).
- Greater size = bigger prey = greater growth.
- Also compensatory growth: mortality & physiology

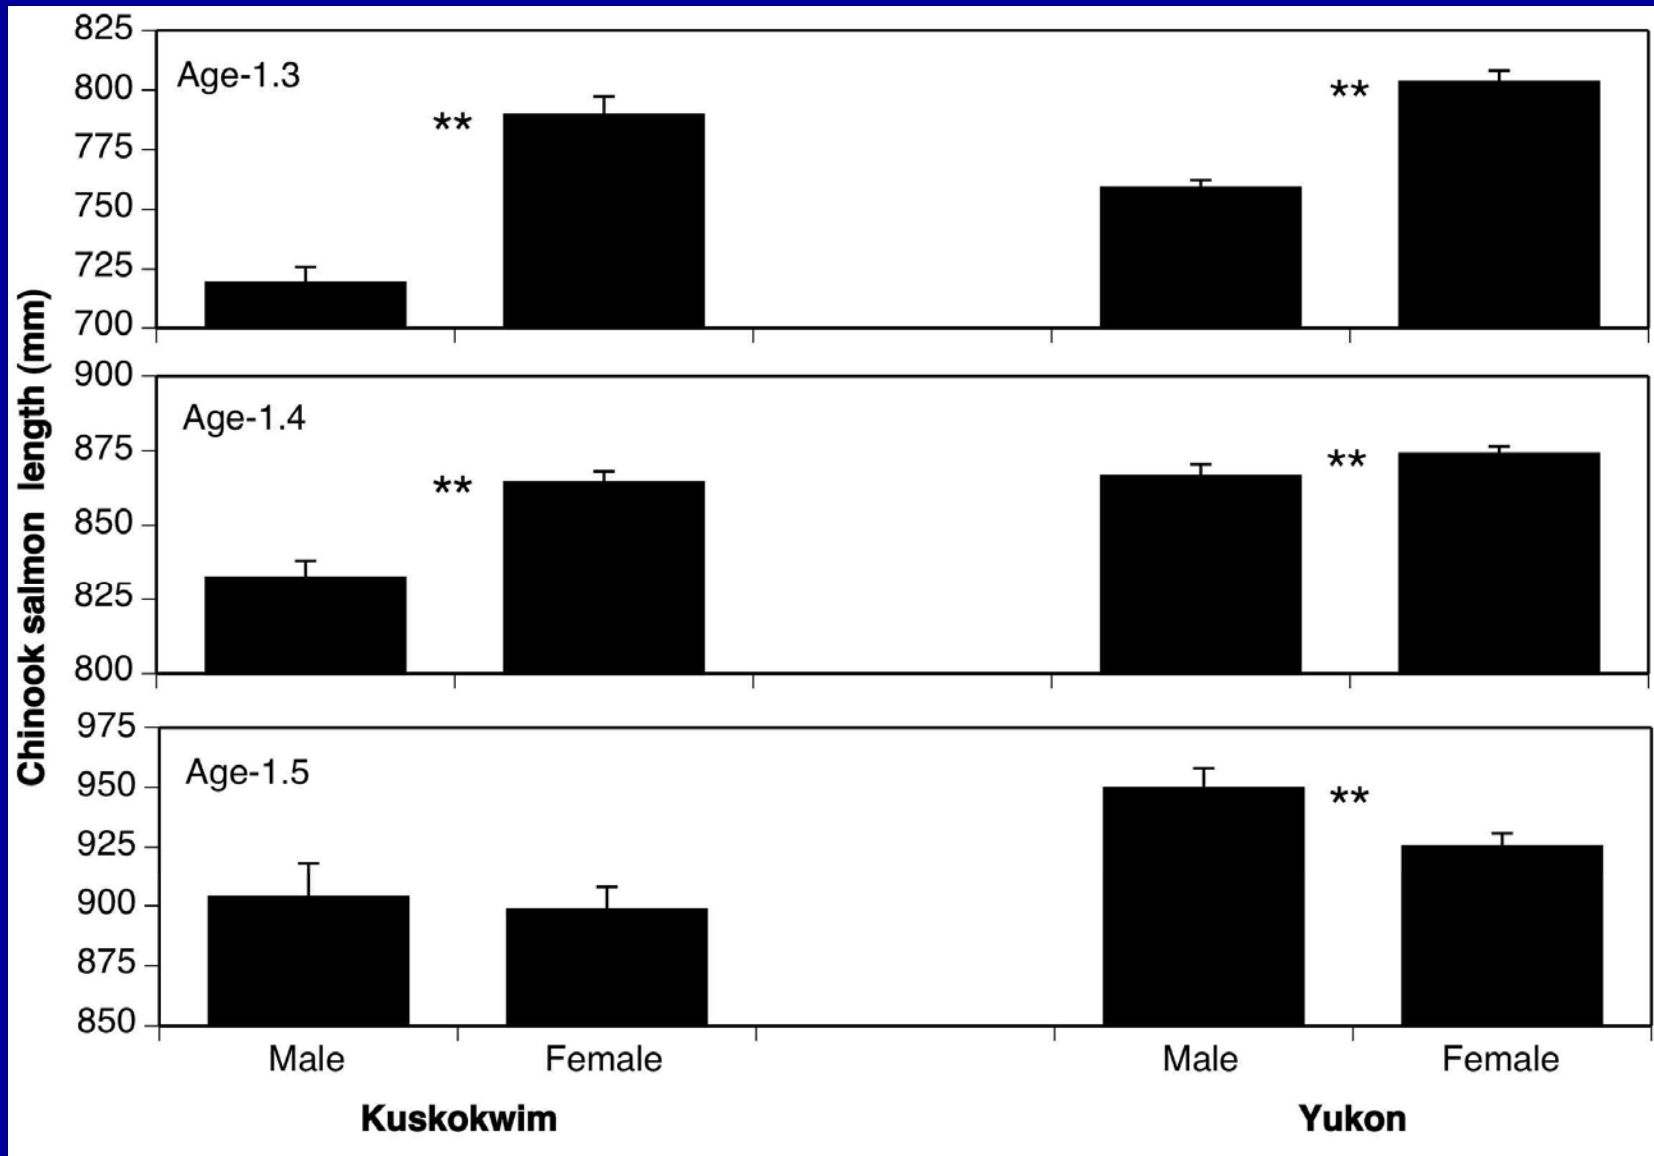

Are Male Chinook Bigger than Female Chinook at Age?

- Sockeye male $>$ female at age.
- Chum male $>$ female at age.
- Coho male $< =$ female (Holtby & Healey 1986).
- Chinook?

Female Chinook are older

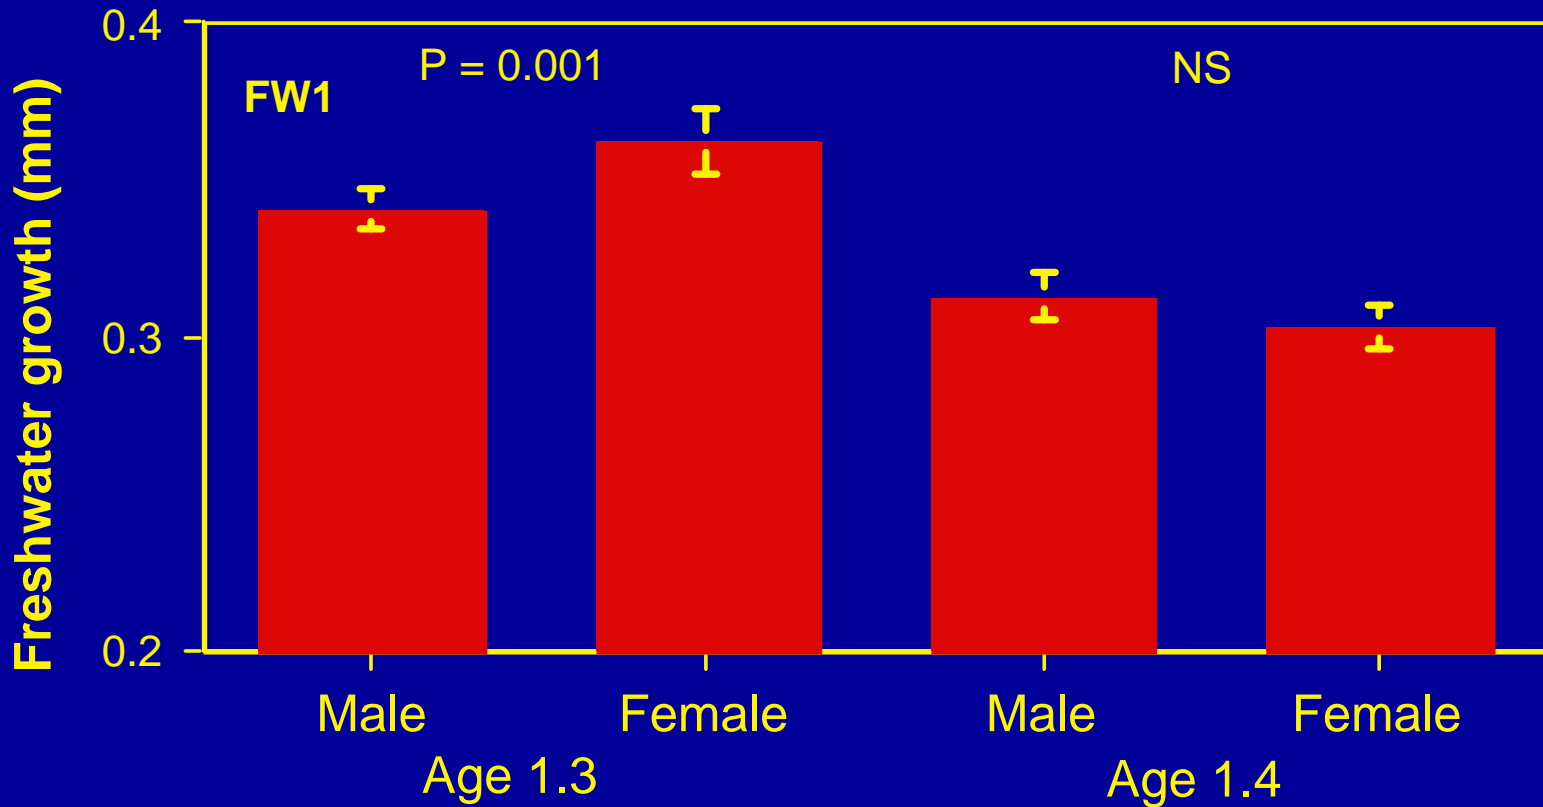

Female Length > Male Length

When Does Differential Growth Begin?

Age 1.3 > Age 1.4 freshwater growth

Age 1.3 Female > Male; Age 1.4 Female = Male

When Does Differential Growth Begin?

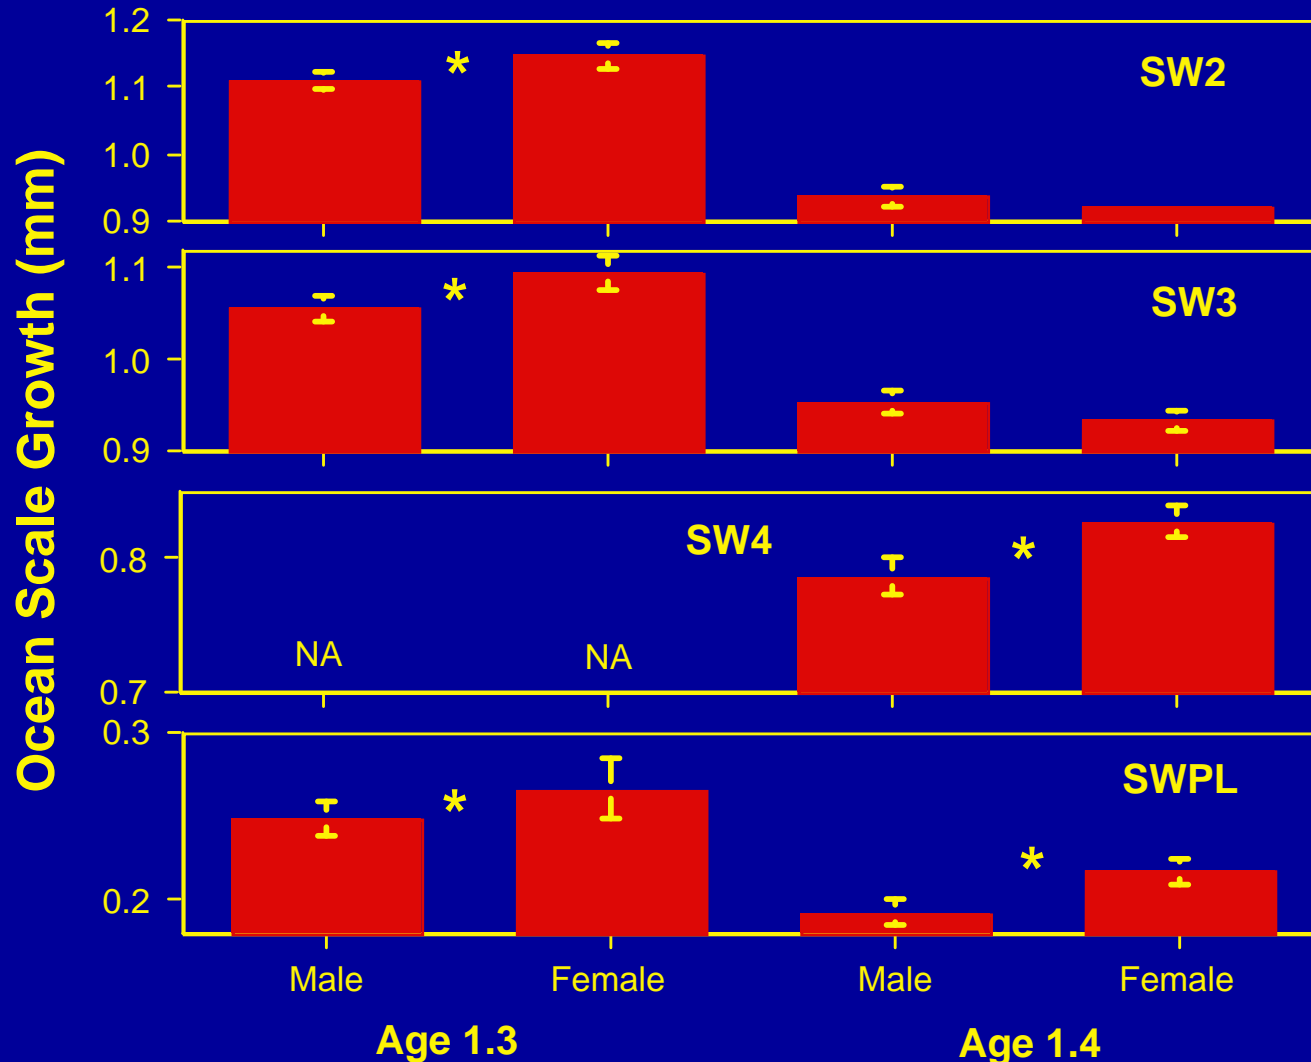

Age 1.3 > Age 1.4 SW1 Growth

Age 1.3 Female > Male

Age 1.3 > Age 1.4 Growth

Age 1.4 Female > Male: Late Life

Differential Chinook Growth: Age & Sex

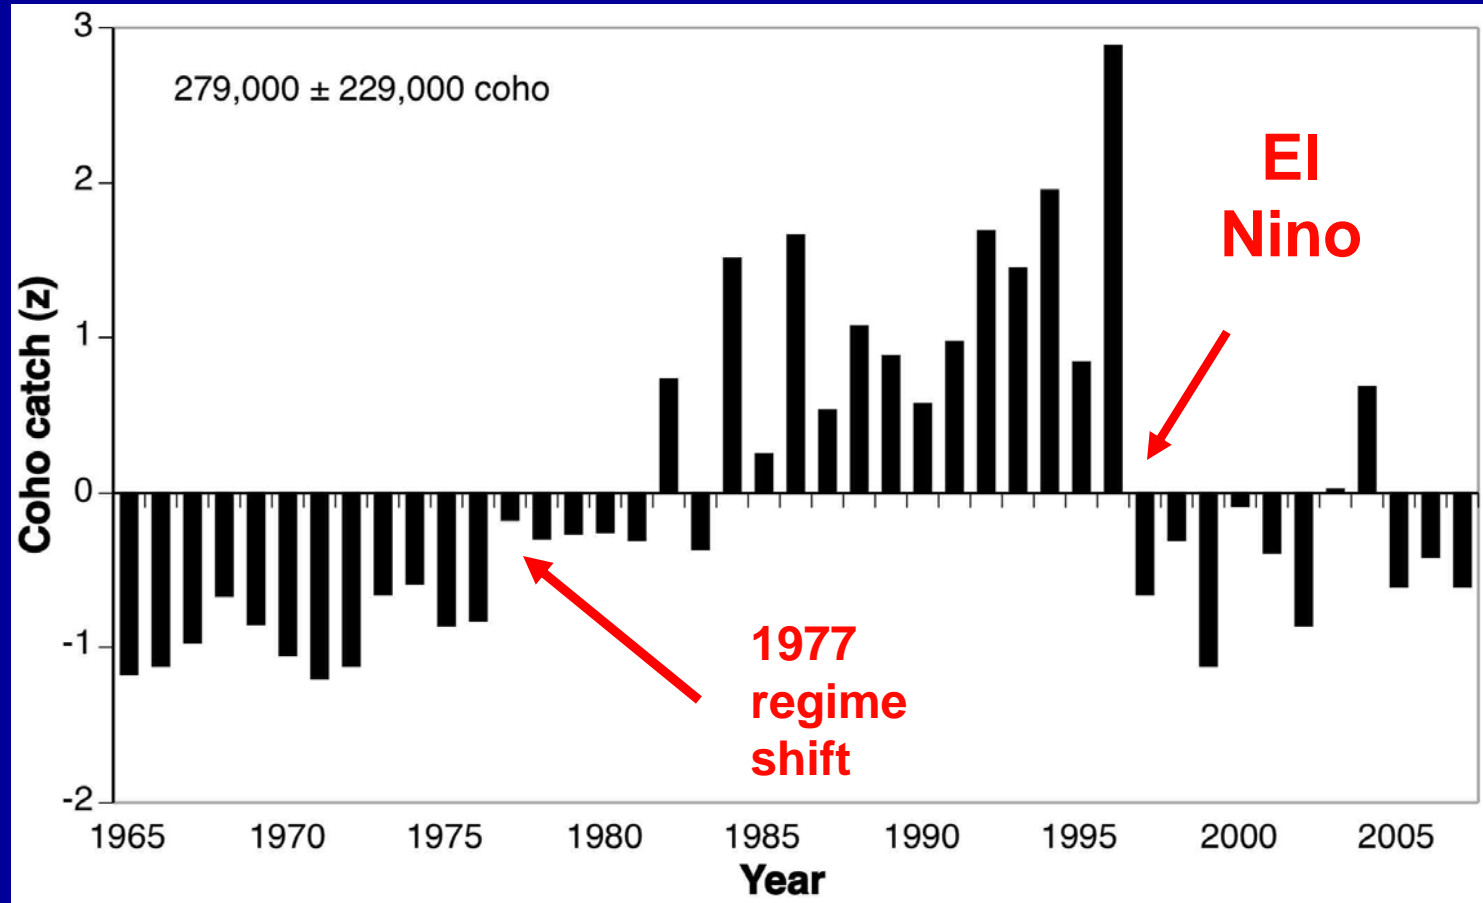

- Age 1.3 grow faster than Age 1.4 Chinook (beginning freshwater).
- Age 1.3: Rapid female growth, all years.
- Age 1.4: Rapid female growth, late life.
- Pattern consistent in Yukon & Kuskokwim Chinook.

Female > Male Chinook Growth

- Larger females: greater egg number & size.
- Tradeoff: mortality risk vs. fecundity.
- Large male size may be less important in Chinook (less competition for mates?).
- Key: grow fast & produce many big eggs.

Kuskokwim Coho

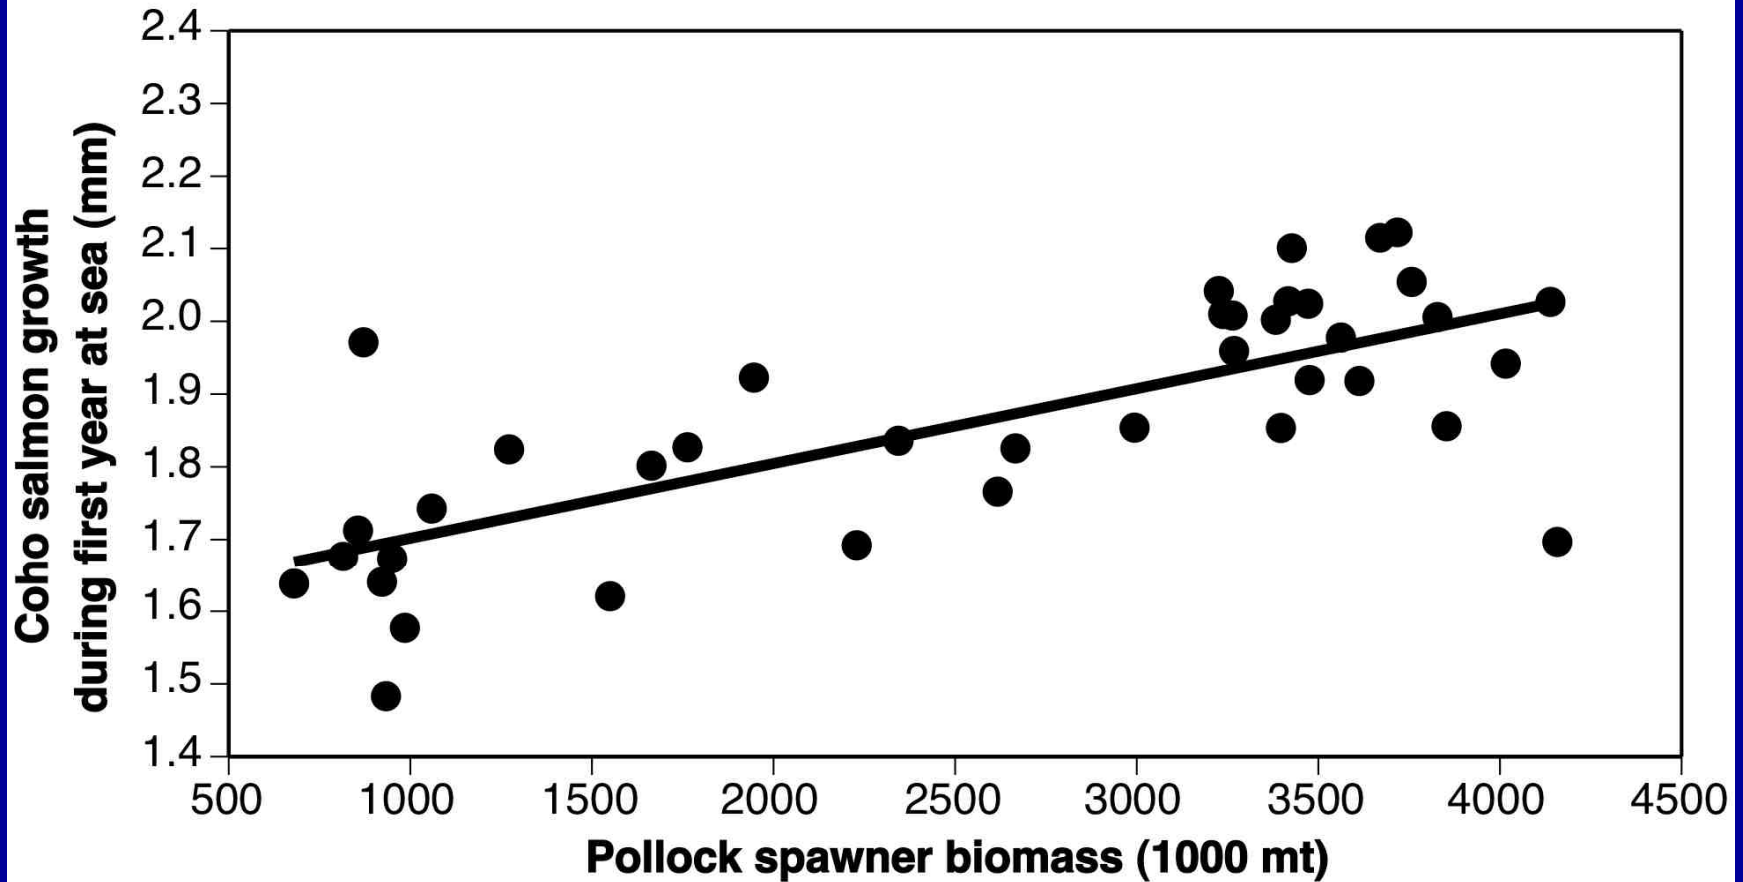

- Largest stock in Alaska
- Sharp decline 1997 El Nino

Coho Growth v. Pollock Larvae

1964-2005

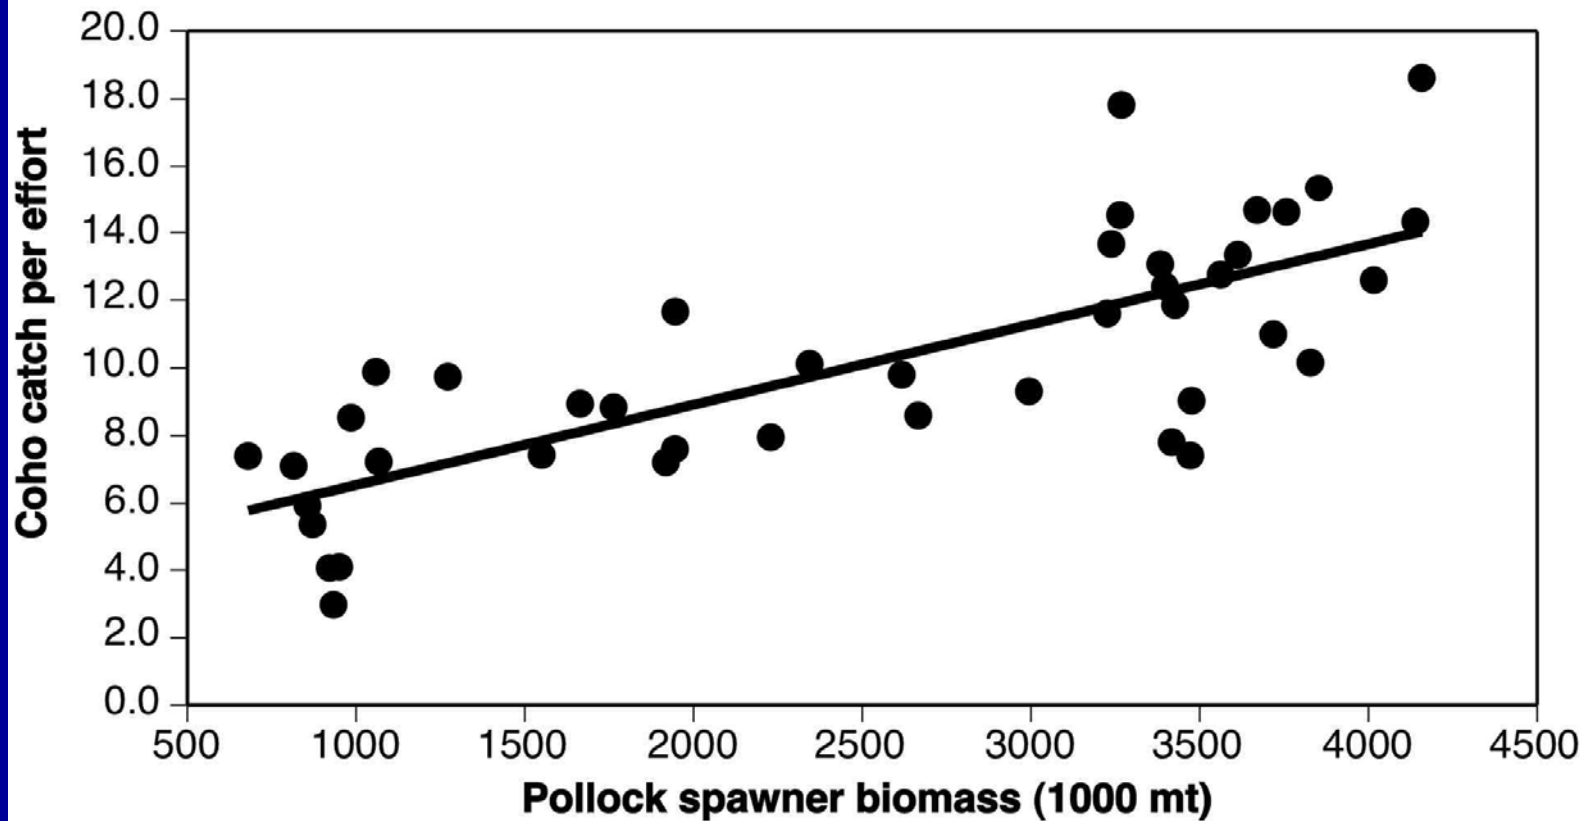

SW1 = 1.53 + .000104 (pollock) + .00017 (pink salmon) $R^2 = 0.60$.

Coho CPUE v. Pollock Larvae

1965-2006

$$\text{CPUE} = 0.643 + .0024 (\text{pollock}) + .029 (\text{pink salmon}) + 3.6 (1977 \text{ shift}) + 6.7 (1989 \text{ shift}) \quad R^2 = 0.80$$

Summary

- Chinook growth was highly dependent on previous growth & not clearly associated with abundance.
- Females larger than males, beginning FW (age 1.3) or late ocean life (age 1.4).
- Age 1.3 > 1.4 size beginning in freshwater.
